Banking on Resolution: Portfolio Effects of Bail-in vs. Bailout

Job market paper

This paper investigates the impact of supervisory resolution tools, specifically bail-ins versus bailouts, on the ex-ante banks' portfolio composition and resulting ex-post default probabilities in the presence of both idiosyncratic and systematic shocks. Banks make decisions regarding short-term versus long-term risky investments taking into account the expected resolution policy. I find that both types of shocks can generate financial instability, which the two resolution tools address through distinct channels. With only idiosyncratic shocks, creditor bailouts, acting as debt insurance, eliminate the equilibrium with bank defaults, while bail-ins induce banks to invest less in the risky short-term asset, which may also prevent defaults. In the presence of both shocks, creditor bailouts can prevent systemic defaults, while bail-ins are less effective in preventing them and could even contribute to systemic risk.

The Effect of Bank Mergers on Lending and Risk-Taking

This paper investigates the effect of bank mergers on banks' loan rates, leverage, and risk-taking. I consider an economy with $n \geq 3$ banks where two of them merge for exogenous reasons. I assume that banks monitor borrowers, which lowers their probability of default, and that monitoring is costly and unobservable which creates a moral hazard problem. With insured deposits as the single source of funding, a merger generates higher loan rates, which in turn increases banks' margins and monitoring intensities. Introducing equity capital as an additional source of funding enhances monitoring incentives, due to a "skin-in-the-game" effect, which increases loan demand. This creates a trade-off that results in nontrivial changes in post-merger capital, loan rates, and risk-taking. If loan rates increase following the merger, both the merged bank and its competitors increase their leverage. Higher loan rates and leverage exert opposing effects on monitoring intensity and, consequently, on risk-taking.

Banking Supervision and Bank Risk-Taking

joint with Rafael Repullo

This paper presents a theoretical analysis of the effects of banking supervision on bank risk-taking. The model features a risk-neutral bank that raises one unit of insured deposits and invests them in a large portfolio of loans. The bank chooses the extent of correlation in defaults, from $\sigma = 0$ (independent defaults) to $\sigma = 1$ (perfectly correlated defaults). The supervisor observes a noisy signal of the default rate (the proportion of loans that will default) and closes the bank early when the signal is above a threshold. The question is: will this combination of supervisory information and supervisory closure reduce risk-taking (the bank's choice of σ)? The paper will shed light on the conditions under which a higher quality of supervisory information and/or a tougher closure rule will reduce banks' risk-taking.
